SQL Injection

Cosa è:

SQL injection è una tecnica di *code injection* dove si inietta del codice SQL

```
# Define POST variables
uname = request.POST['username']
passwd = request.POST['password']

# SQL query vulnerable to SQLi
sql = "SELECT id FROM users WHERE username=''" + uname + "'" AND password=''" + passwd + "'"

# Execute the SQL statement
database.execute(sql)
```

<https://www.acunetix.com/websitesecurity/sql-injection/>

Come si combatte?

Semplicemente usando: **prepared statements and parameterized queries**

```
$stmt = $dbConnection->prepare('SELECT * FROM employees WHERE name = ?');  
$stmt->bind_param('s', $name);
```

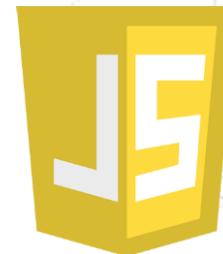

Oppure pulendo tutti gli input:

```
mysqli_real_escape_string ( mysqli $link , string $escapestr ) : string
```

This function is used to create a legal SQL string that you can use in an SQL statement. The given string is encoded to an escaped SQL string, taking into account the current character set of the connection.

```
$unsafe_variable = $_POST["user-input"];  
$safe_variable = mysqli_real_escape_string($unsafe_variable);  
mysql_query("INSERT INTO table (column) VALUES ('" . $safe_variable . "')");
```

Javascript

JavaScript was initially created to “make web pages alive”.

Scripts are provided and executed as plain text. They don't need special preparation or compilation to run.

```
<!DOCTYPE html>
<html>
<body>

<h2>JavaScript Statements</h2>

<p>A <b>JavaScript program</b> is a list of <b>statements</b> to be executed by a computer.</p>

<p id="demo"></p>

<script>
var x, y, z; // Declare 3 variables
x = 5; // Assign the value 5 to x
y = 6; // Assign the value 6 to y
z = x + y; // Assign the sum of x and y to z

document.getElementById("demo").innerHTML =
"The value of z is " + z + ".";
</script>

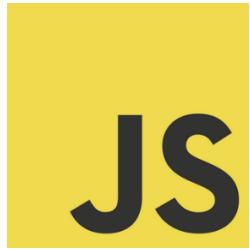

</body>
</html>
```

Javascript

Javascript è un linguaggio debolmente tipizzato

<https://hacks.mozilla.org/2017/02/a-crash-course-in-just-in-time-jit-compilers/>

```
function arraySum(arr) {  
    var sum = 0;  
    for (var i = 0; i < arr.length; i++) {  
        sum += arr[i];  
    }  
}
```

Javascript

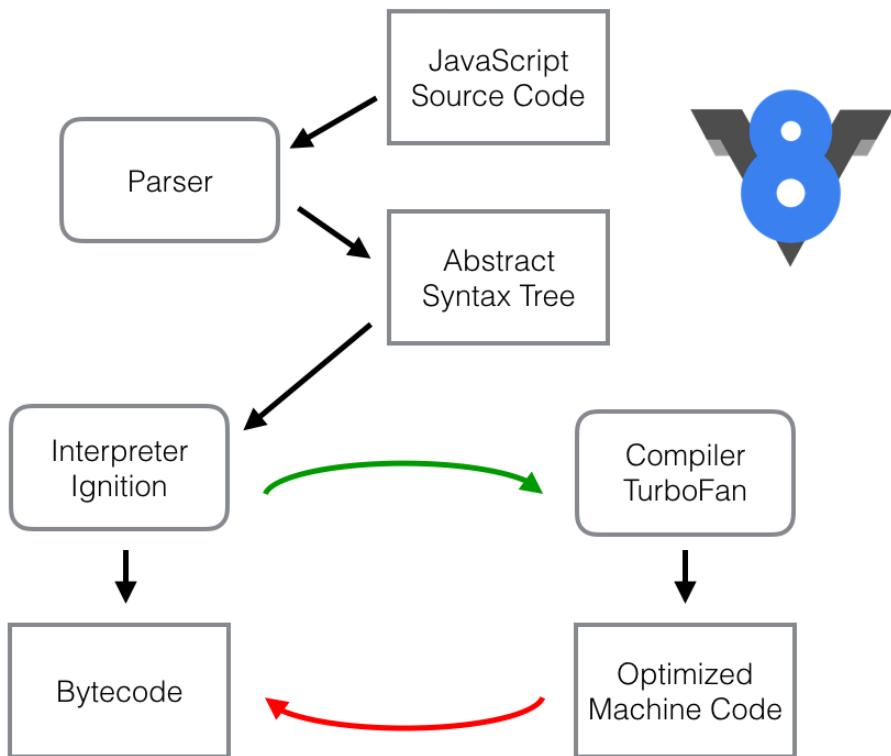

(SpiderMonkey)

(Nitro)

1. The engine (embedded if it's a browser) reads ("parses") the script.
2. Then it converts ("compiles") the script to the machine language.
3. And then the machine code runs, pretty fast.

Javascript

JavaScript is always synchronous and single-threaded.
If you're executing a JavaScript block of code on a page
then no other JavaScript on that page will currently be
executed.

synchronous, single thread of control

synchronous, two threads of control

asynchronous

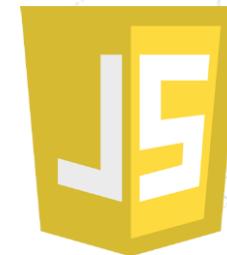

Javascript – Callback and Promise

One approach to asynchronous programming is to make functions that perform a slow action take an extra argument, a *callback function*. The action is started, and when it finishes, the callback function is called with the result.

```
setTimeout(() => console.log("Tick"), 500);
```

A *promise* is an asynchronous action that may complete at some point and produce a value. It is able to notify anyone who is interested when its value is available.

```
let fifteen = Promise.resolve(15);
fifteen.then(value => console.log(`Got ${value}`));
```

Javascript – Callback and Promise

JavaScript Program

```
Function baz() {  
    console.log('Hello from baz');  
}  
  
Function bar() {  
    baz();  
}  
  
Function foo() {  
    bar();  
}  
  
foo();
```

Javascript – Callback and Promise

The screenshot shows the loupe browser extension interface. On the left, a code editor window displays the following JavaScript code:

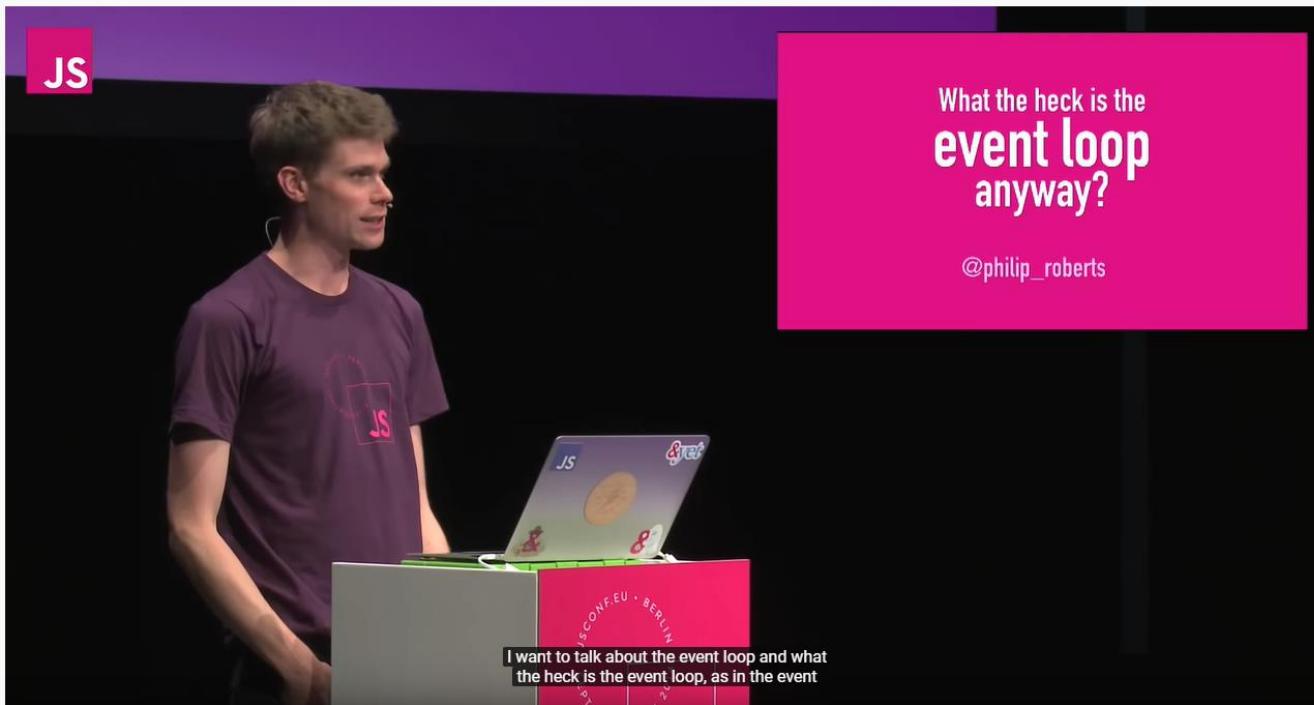

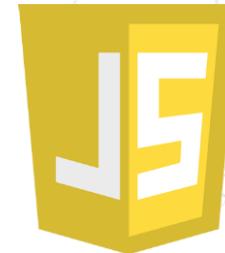

```
1
2
3  function printHello() {
4      console.log('Hello from baz');
5  }
6
7  function baz() {
8      setTimeout(printHello, 3000);
9  }
10
11 function bar() {
12     baz();
13 }
14
15 function foo() {
16     bar();
17 }
18
19 foo();
```

Below the code editor are two buttons: "Click me!" and "Edit". To the right of the code editor are three panels: "Call Stack", "Web APIs", and "Callback Queue". The "Call Stack" panel is currently active, indicated by a dashed border. It contains a large orange circular arrow icon. The "Web APIs" and "Callback Queue" panels are also visible with dashed borders. A mouse cursor is shown hovering over the "Callback Queue" panel. At the bottom of the interface is a navigation bar with icons for back, forward, and search.

MD5 for passwords

93

Using salted md5 for passwords is a bad idea. Not because of MD5's cryptographic weaknesses, but because it's fast. This means that an attacker can try billions of candidate passwords per second on a single GPU.

What you should use are deliberately slow hash constructions, such as scrypt, bcrypt and PBKDF2. Simple salted SHA-2 is not good enough because, like most general purpose hashes, it's fast. Check out [How to securely hash passwords?](#) for details on what you should use.

Scoprite se siete stati **pwned**

A corruption of the word "Owned." This originated in an online game called Warcraft, where a map designer misspelled "owned." When the computer beat a player, it was supposed to say, so-and-so "has been owned."

Instead, it said, so-and-so "has been pwned."
